

# AI-Based Network Topology Optimization

---

**ITU AI/ML in 5G Challenge**

**Weeny Wit**

**December 2020**

# Problem Description (1): Background

---

The existing network topology planning does not fully consider the increasing network traffic and uneven link capacity utilization, resulting in difficult topology optimization and increasing investments in network construction.

Network structure needs to be optimized in a dynamic manner based on the traffic change predicted through AI technologies, to ensure link load balancing when network traffic increases.

This improves network resource utilization, and thus reduce the investments in network capacity expansion.

---

Rules: 1) Number of nodes per link  $\leq 30$  2) Edges available for addition  $\leq 500$  meters 3) Start and tail nodes of any main link should be G or H

Recommendation ITU-T Y.3175

# Our Solution

## Data processing

Set the value of missing traffic to 0 and sort out traffic by network element

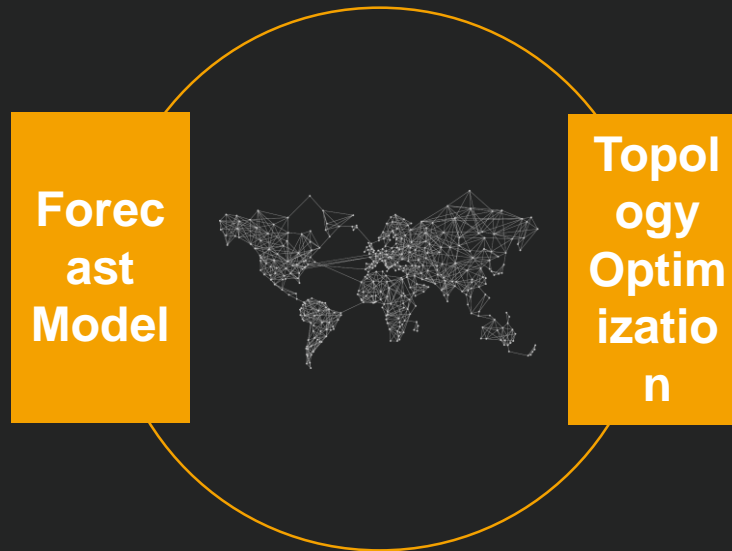

## Training for traffic forecast

Use the TensorFlow to build an LSTM neural model.

Input data to the model for training, and achieve the traffic of the next 10 days.

## Data post-processing

Sort out the forecast traffic of the next 10 days by day

## Topology building

Use NetworkX to build network topology and set up the neighbor node library.

## Topology recovery

Use the "DFS algorithm" to discover main links, sort out cross-connected links, find out sublinks and hanging links via the Node-Removing Method, and build a link set.

## Topology optimization

Deal with links with heavy and low loads via link combination and partial link optimization

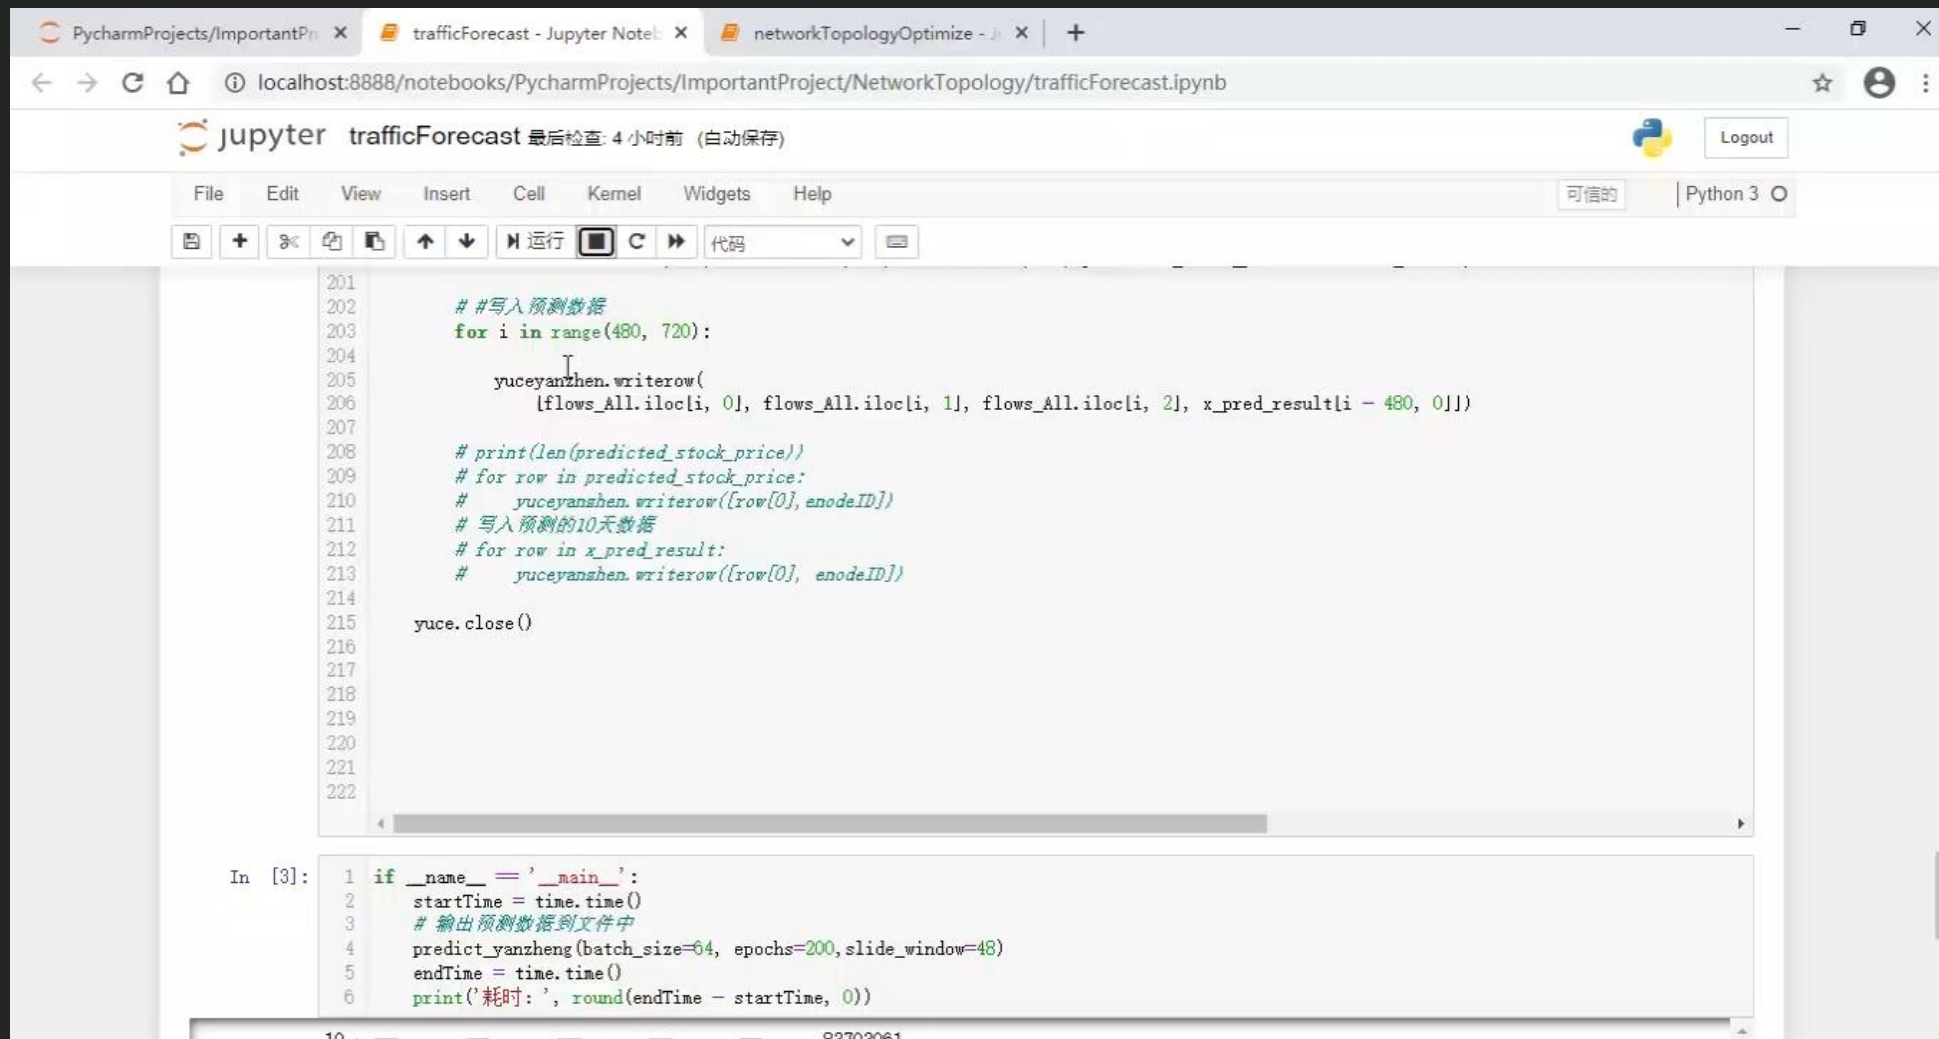

## Iteration for optimum topology

Implement successive iteration for 24 hours and select the optimum topology from the total 25 topology.

## Topology restructuring

Topology restructuring is to optimize the links with heavy or low loads for a long period of time. The newly added edges are included in the source topology of the next iteration.

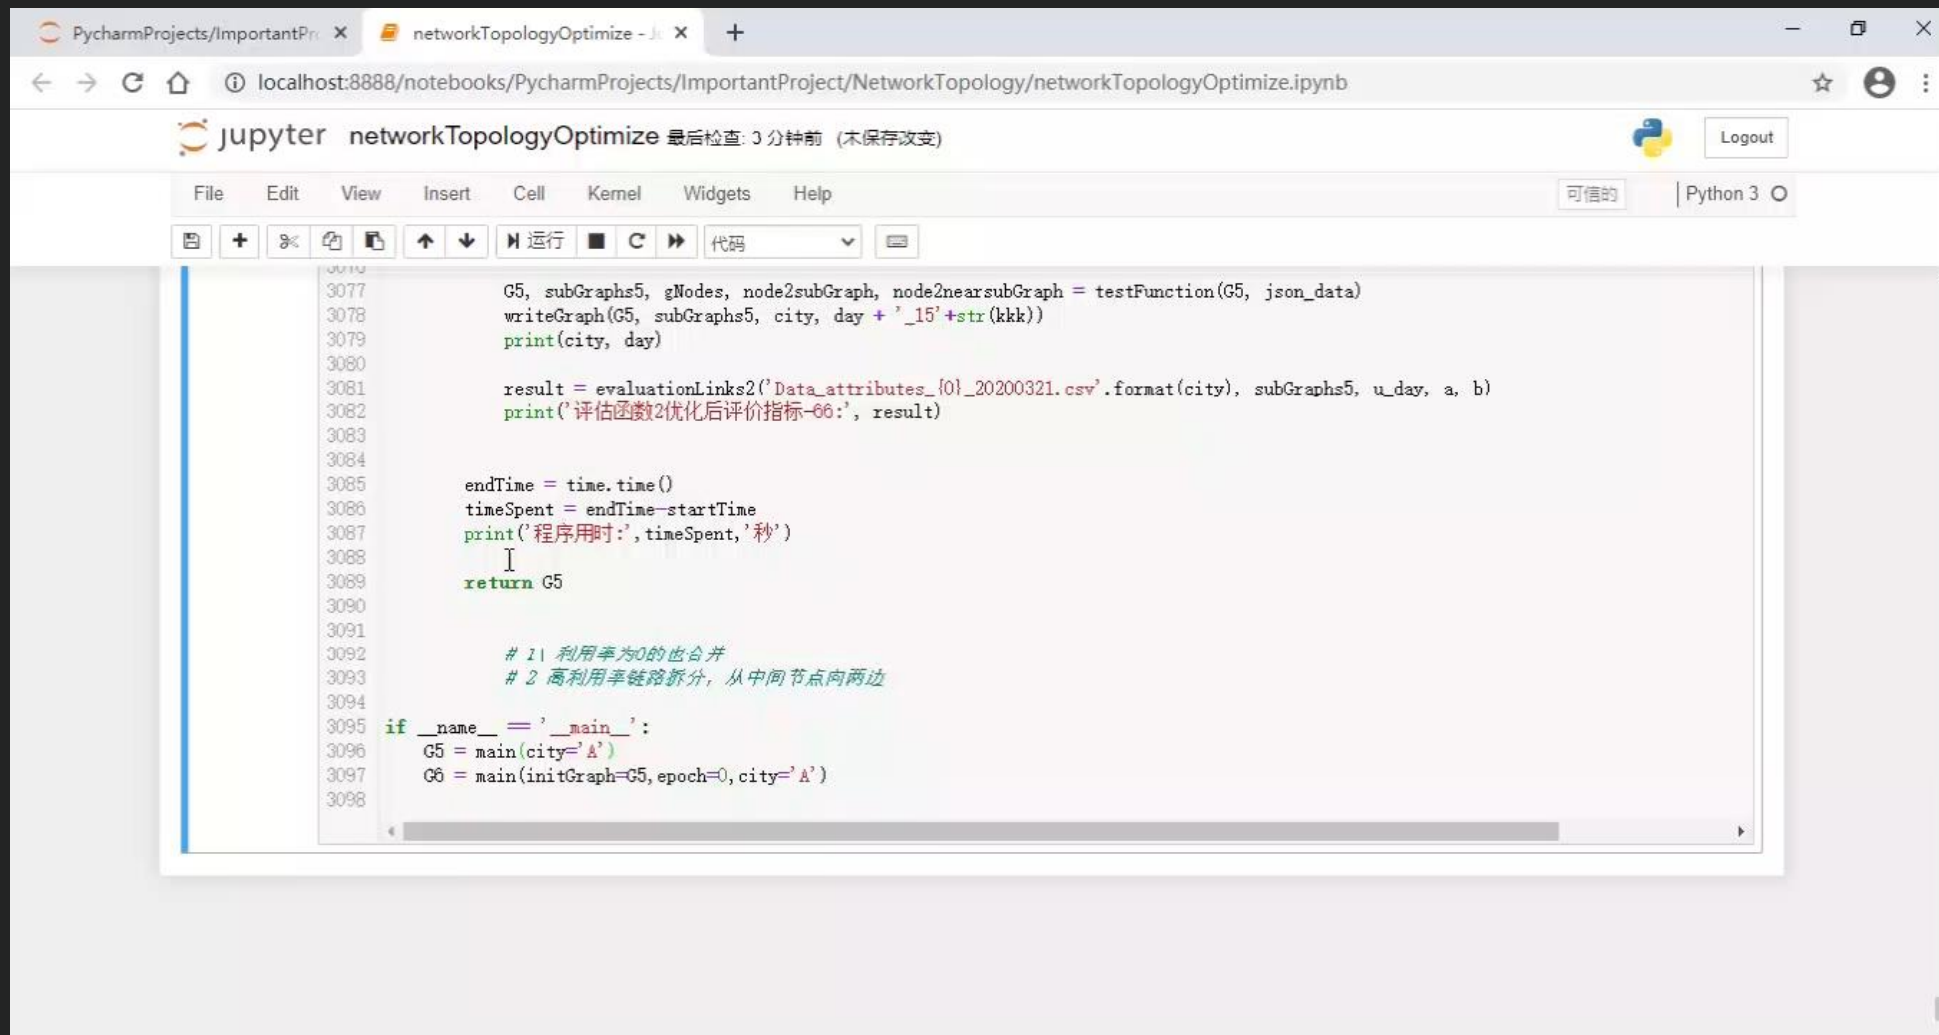

# Our Solution

```
201
202     ##写入预测数据
203     for i in range(480, 720):
204
205         yuceyanzhen.writerow(
206             [flows_All.iloc[i, 0], flows_All.iloc[i, 1], flows_All.iloc[i, 2], x_pred_result[i - 480, 0]])
207
208     # print(len(predicted_stock_price))
209     # for row in predicted_stock_price:
210     #     yuceyanzhen.writerow([row[0], enodeID])
211     # 写入预测的10天数据
212     # for row in x_pred_result:
213     #     yuceyanzhen.writerow([row[0], enodeID])
214
215     yuce.close()
216
217
218
219
220
221
222

In [3]: 1 if __name__ == '__main__':
2         startTime = time.time()
3         # 输出预测数据到文件中
4         predict_yanzheng(batch_size=64, epochs=200, slide_window=48)
5         endTime = time.time()
6         print('耗时:', round(endTime - startTime, 0))
```

# Our Solution

The image shows a Jupyter Notebook interface with a code cell containing Python code for network topology optimization. The code includes functions for testing, writing graphs, evaluating links, and calculating execution time. It also features a main function and a main execution block.

```
3077 G5, subGraphs5, gNodes, node2subGraph, node2nearsubGraph = testFunction(G5, json_data)
3078 writeGraph(G5, subGraphs5, city, day + '_15'+str(kkk))
3079 print(city, day)
3080
3081 result = evaluationLinks2('Data_attributes_{0}_20200321.csv'.format(city), subGraphs5, u_day, a, b)
3082 print('评估函数2优化后评价指标-G6:', result)
3083
3084
3085 endTime = time.time()
3086 timeSpent = endTime-startTime
3087 print('程序用时:', timeSpent, '秒')
3088
3089 return G5
3090
3091
3092 # 1 利用率为0的也合并
3093 # 2 高利用率链路拆分, 从中间节点向两边
3094
3095 if __name__ == '__main__':
3096     G5 = main(city='A')
3097     G6 = main(initGraph=G5, epoch=0, city='A')
3098
```

# Our Solution

Link display

# Highlights (1): Enhanced LSTM Traffic Forecast Model for Traffic Change

We built an **LSTM neural network model** with TensorFlow, input 480 samples of per-NE traffic of the last 20 days into the model, and selected appropriate parameters with integrated consideration of three factors. The ratio of errors in traffic forecast is **reduced to 3%**. With distributed and multiprocessing technologies, the operating efficiency is **increased by 20 times**.

Comparison of **Epochs**, select 200

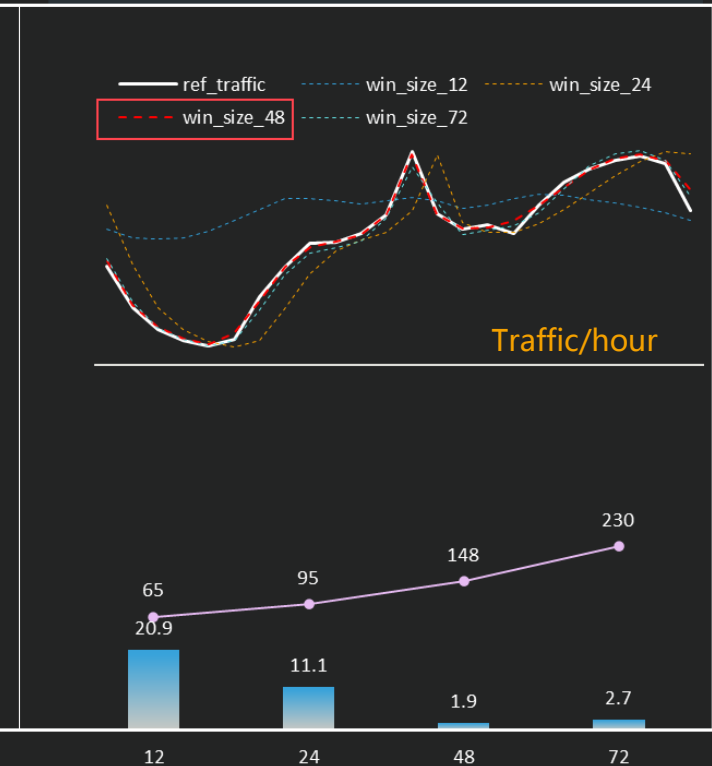

Notes: batch\_size=64, slide\_window=48

Comparison of **Batch\_size**, select 64

Notes: epochs=200, slide\_window=48

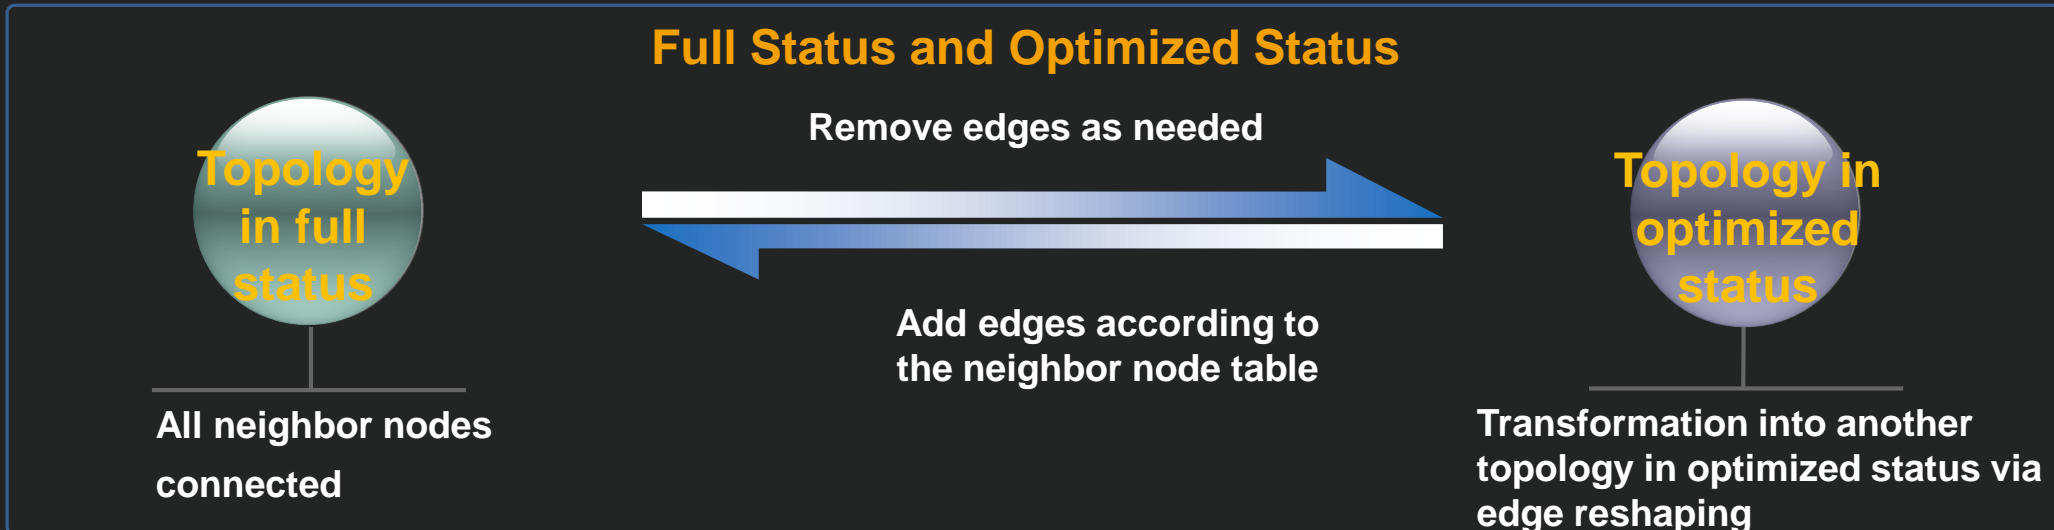

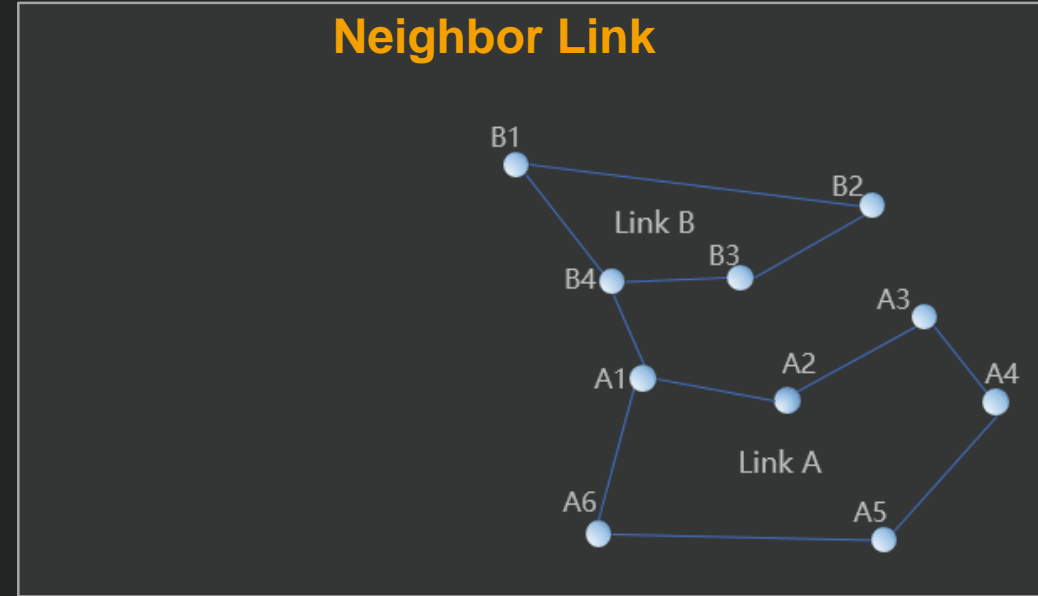

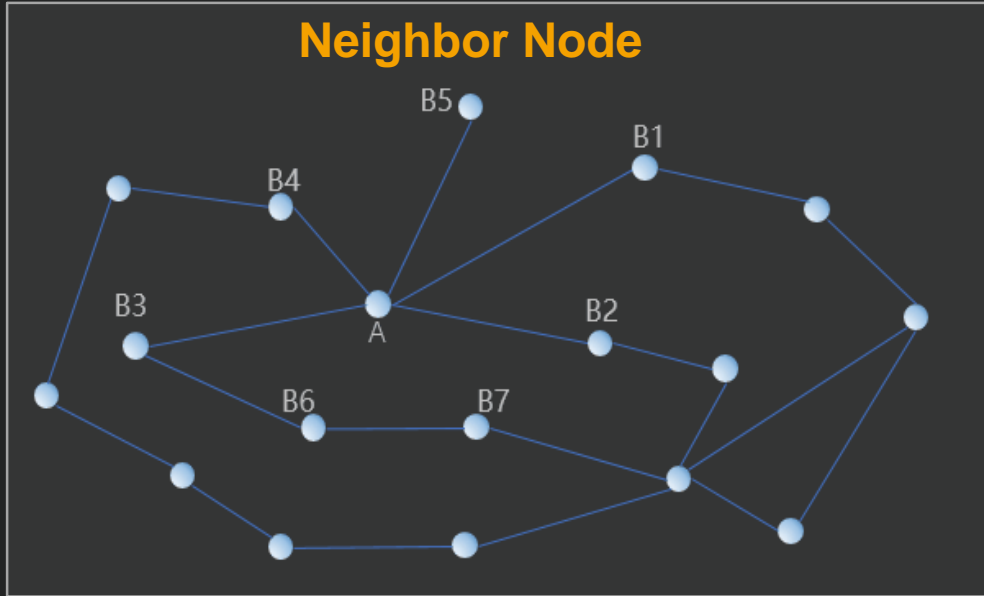

Comparison of **slide\_window**, select 48

Notes: epochs=200, batch\_size=64

# Highlights (2): Topology in Full Status and Topology in Optimized Status

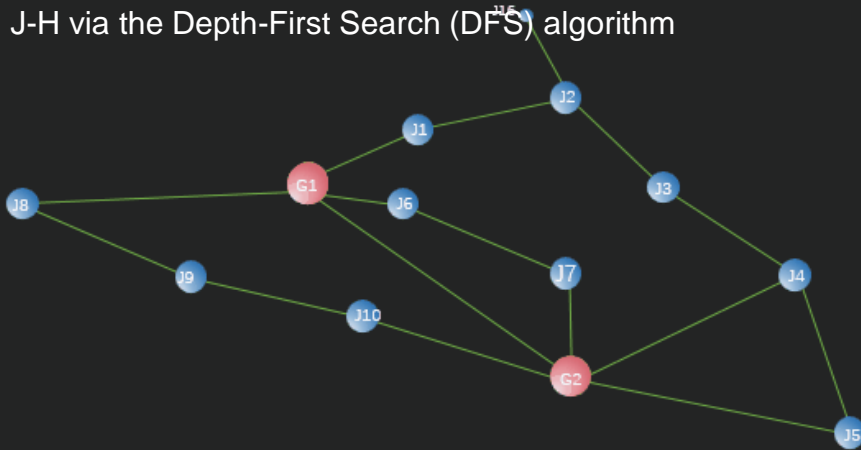

The concept of neighbor nodes and links reduces the number of iterations

# Highlights (3): DFS + Node Removing Method to Accelerate Topology Recovery

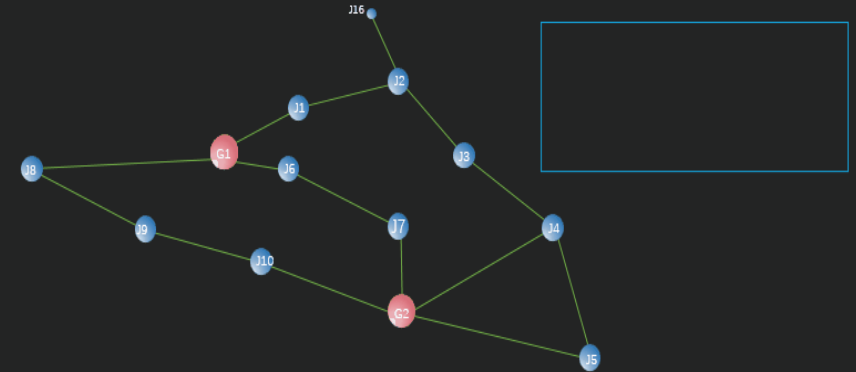

## Search for main links

Execute the searchMainLink function to search for main links in the form of G-H-G or G-J-H via the Depth-First Search (DFS) algorithm

## Sort out cross-connected main links

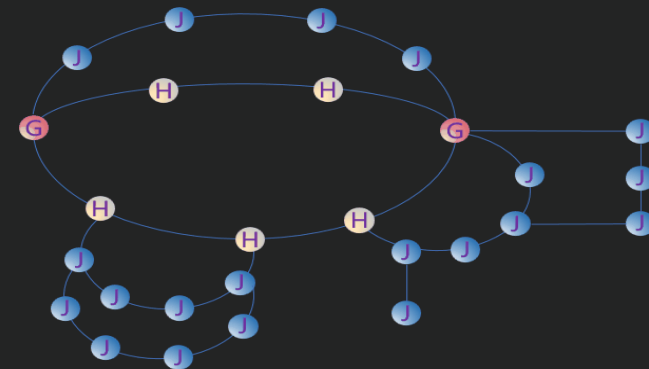

Execute the filterLinks function to remove the main links that are comparatively shorter from the cross-connected main links

## Analyze sublinks and hanging links with our Node-Removing Method

1. Select one main link and remove it
2. Execute connected\_components to identify all connected subgraphs
3. Review all these subgraphs, and identify the main link for those removed sublinks and hanging links
4. Continue to remove other main links

The optimization time was shortened by 80%

Link List

# Highlights (4) : Topology Optimization from Multiple Perspectives

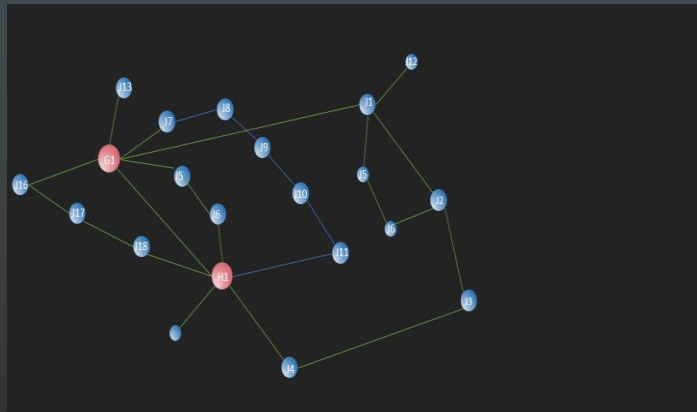

## Link combination

Combine the link with unbalanced utilization with an appropriate neighbor link

## Partial link optimization

Transfer the sublink or hanging link with unbalanced utilization to an appropriate neighbor link if the link combination cannot be implemented

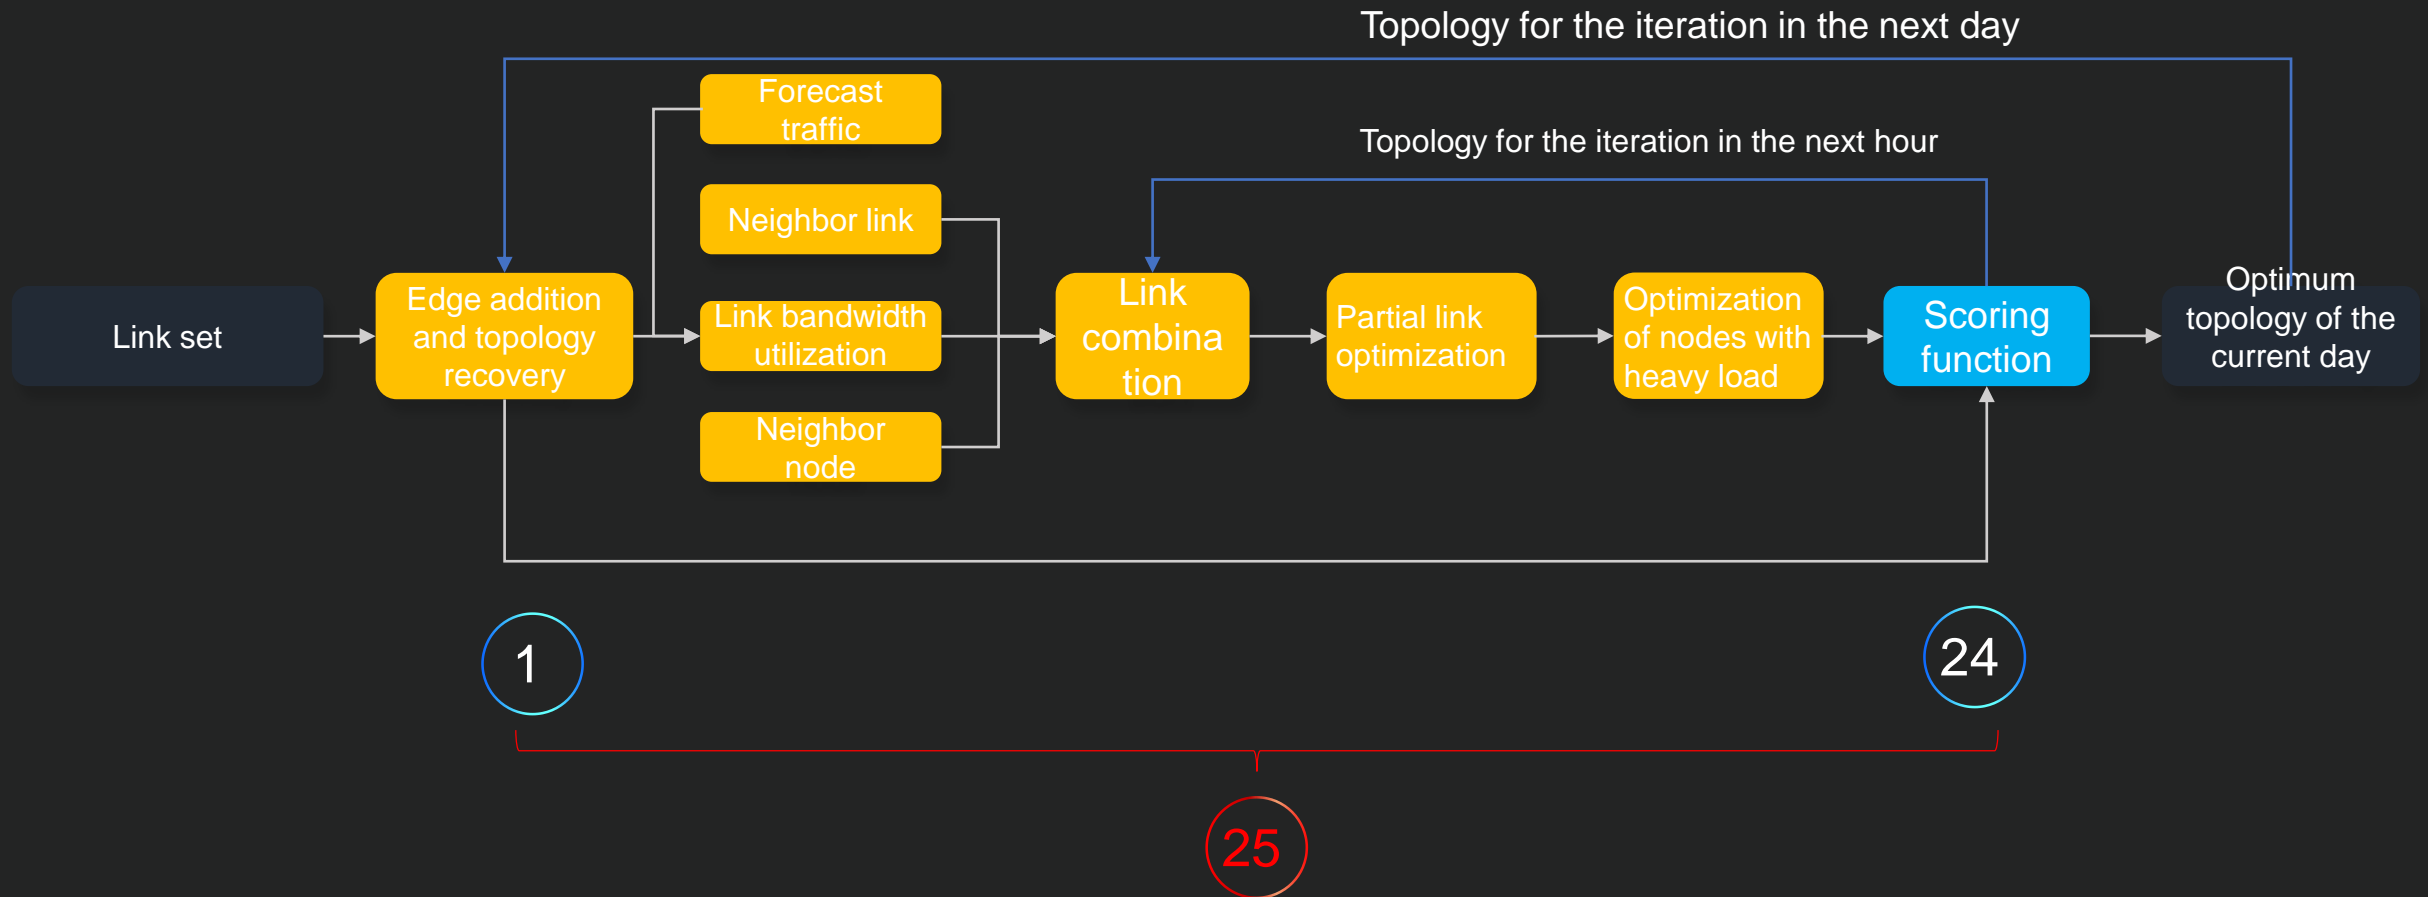

## Optimization by node transfer

Optimize the link with heavy load by transferring some nodes with heavy load on this link to other links

# Highlights (5): Successive Iteration for Optimum Topology

Calculate bandwidth utilization of the topology to be optimized based on the traffic data per 24 hours. After iteration for 25 times a day, select the optimum topology of the current day.

# Highlights (6): Topology Restructuring

1. Find out the links with high or low loads for 10 successive days.
2. Split the link with heavy loads into two links by connecting it with the nodes on a neighbor main link (including node G, H and J), and start the iteration of the new topology with edges added in the previous step to improve the utilization of all links

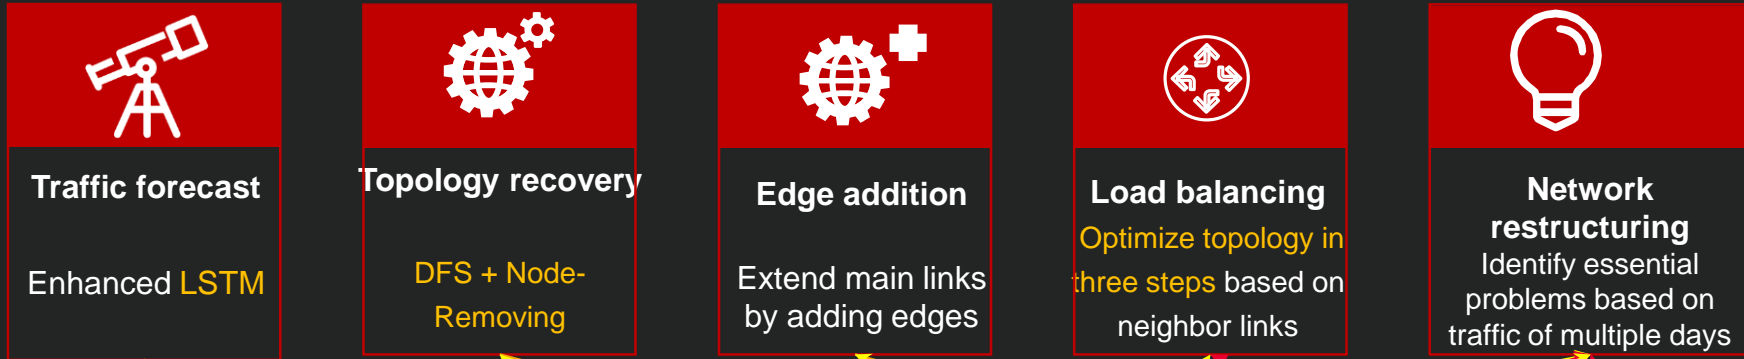

Scenario 1

Scenario 2

# Highlights (7): A Complete Network Topology Analysis and Optimization System

**Systematic processes**

**Input & Output**

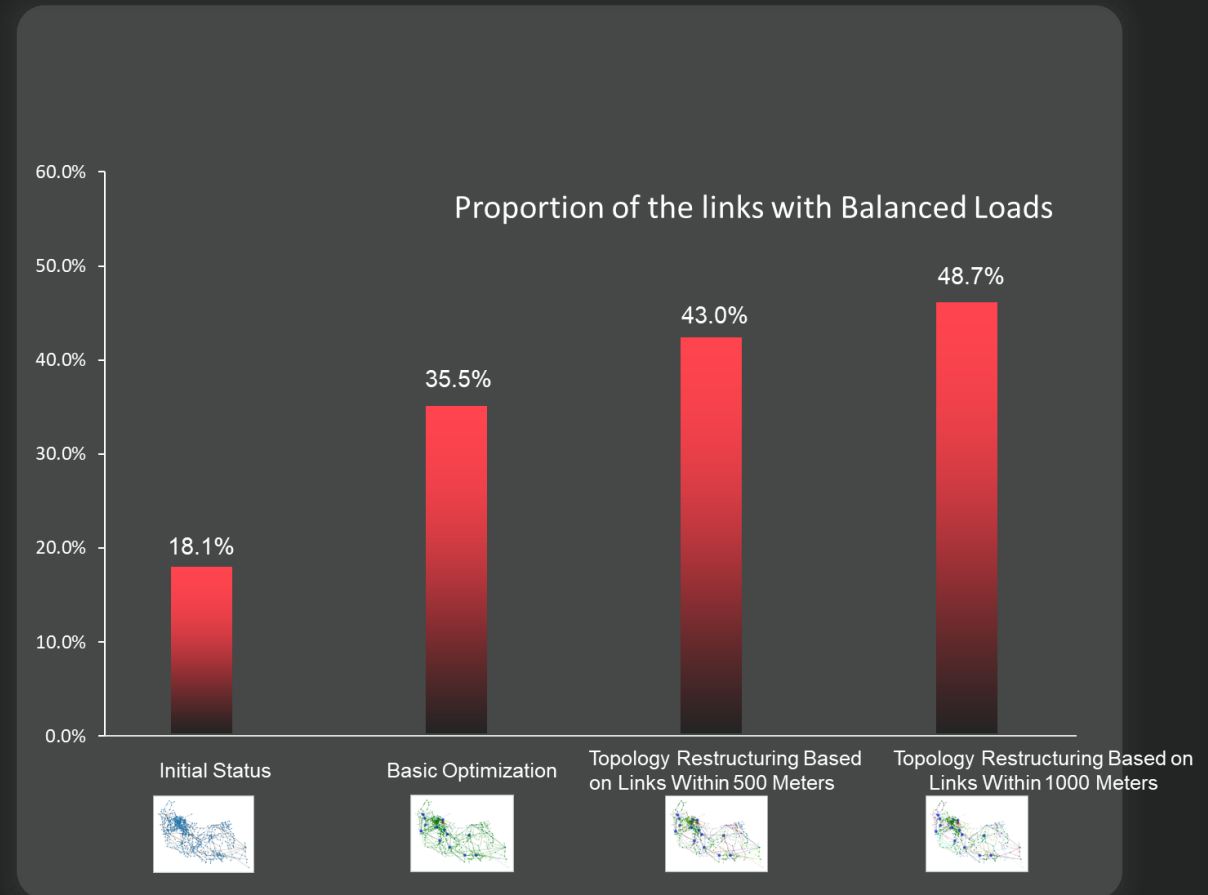

# Effect of the Model

**96% improvement via optimization**  
**169% increase via topology restructuring**

**The proportion of links with balanced load in different optimization stages**

# Feedback

## Comments by the Judges

- Network topology optimization, one of the most challenging tasks requiring professional knowledge
- Propose innovative approach to increase the proportion of load balancing link and predict traffic accurately
- The complete topology analysis and optimization system and the unique algorithm help to increase the proportion of the links with balanced load by 169%
- **Rank No.1 with the highest scores in both** algorithm and final evaluation
- Good generalization and practicality

**First Prize in ITU AI/ML in 5G Challenge (China)**
