Current Diagnostics are threshold classifiers or images that require visual interpretation

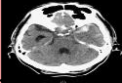

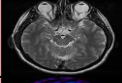

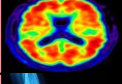

Threshold based diagnostics

Biochemical assays	
Microbiological assays	
immunoblot analysis	

Disease detection for Diabetes, Liver anomalies, Kidney issues etc.

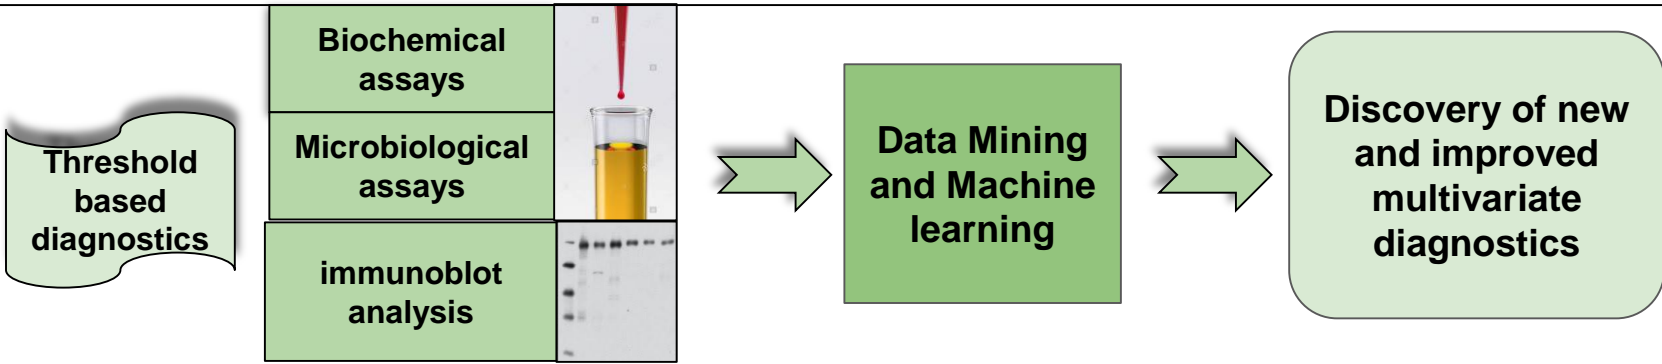

Visual inspection based diagnostics

Histopathological	
CT-scan	
MRI	
PET	
Radiology	
Ultrasound	

Detection of tumors, artifacts and inflammations.

Machine Learning can be used to identify new multivariate diagnostics and automate visual interpretation

SEEK and you may find cancer earlier

Many cancers can be cured by surgery and/or systemic therapies when detected before they have metastasized. This clinical reality, coupled with the growing appreciation that cancer's rapid genetic evolution limits its response to drugs, have fueled interest in methodologies for earlier detection of the disease. Cohen *et al.* developed a noninvasive blood test, called CancerSEEK that can detect eight common human cancer types (see the Perspective by Kalinich and Haber). The test assesses eight circulating protein biomarkers and tumor-specific mutations in circulating DNA. In a study of 1000 patients previously diagnosed with cancer and 850 healthy control individuals, CancerSEEK detected cancer with a sensitivity of 69 to 98% (depending on cancer type) and 99% specificity.

Machine Learning can be used to identify new multivariate diagnostics and automate visual interpretation

a

BRACAnalysis

Test your risks for breast and ovarian cancers with BRACAnalysis. The innovator's BRCA test. For breast/ovarian cancer and family members.

Prolaris

Guideline recommended test for treatment planning. For prostate cancer.

EndoPredict

Decide if you can safely avoid chemotherapy and how beneficial chemotherapy would be. For breast cancer.

MyRisk

Test for your risk to cancer and get medical management recommendations. For individuals/family history of cancer.

Novel diagnostics and risk predictors can be identified from modern DNA/RNA sequencing methods

Epigenetic changes like CpG island hypomethylation or hypermethylation can be used as potential biomarkers in risk stratification and therapeutic response generation for various diseases like colorectal cancer, glioblastoma, breast cancer, asthma, neurodegenerative diseases etc.

Detection of relative abundance of transcript copies with tissue-specific effects is done commonly for cancer diagnosis and can also be used for detecting differentially expressed variants.

The impact of genomic variations can be understood from protein structure, dynamics and network analysis

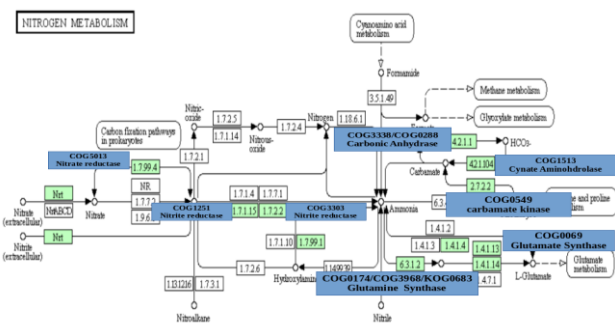

Genetic variations (SNPs, Indel and structural variations)

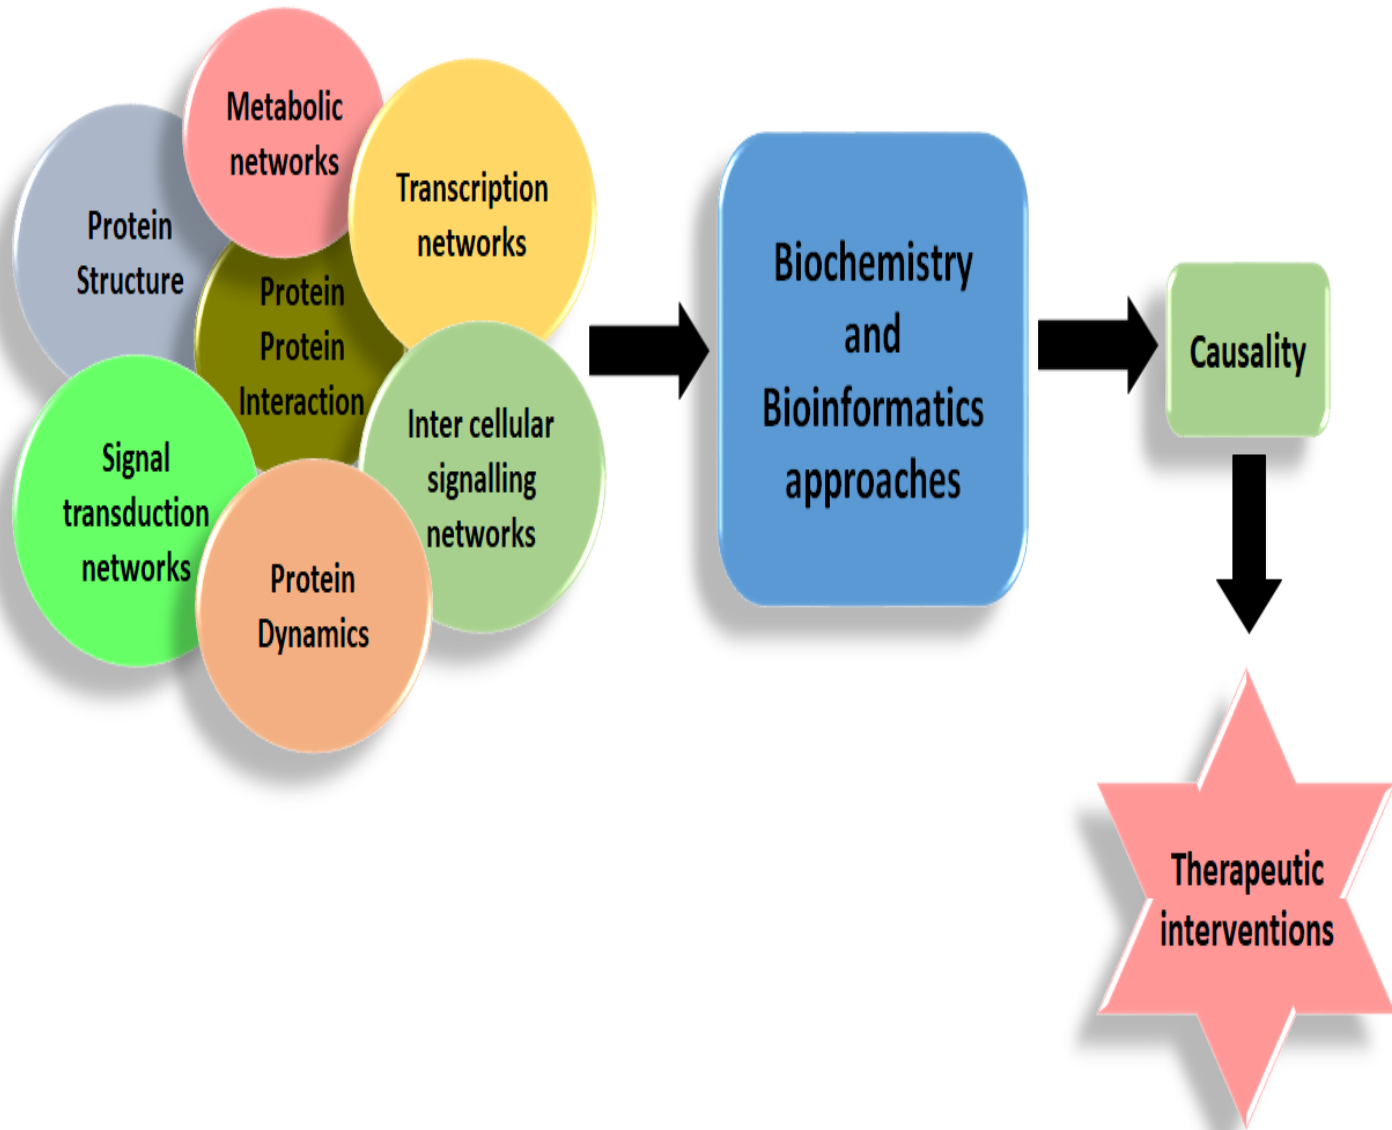

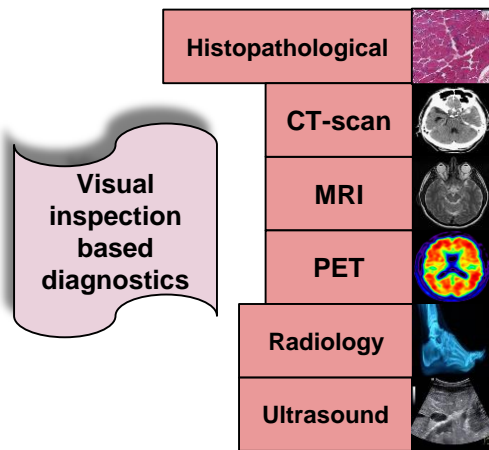

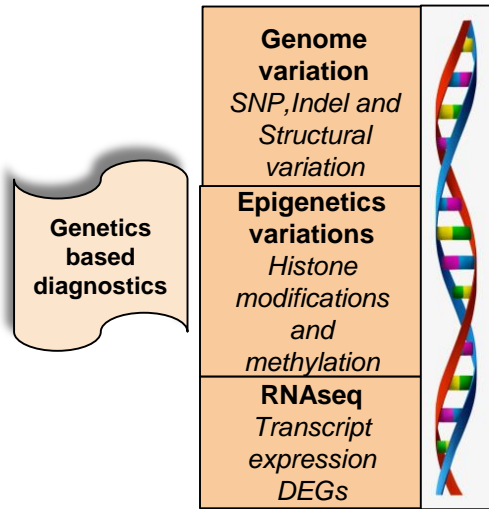

Protein 3D structure (PDB)

Understanding of protein's function and its role in disease

Network based modelling (STRING, Kegg Pathways)

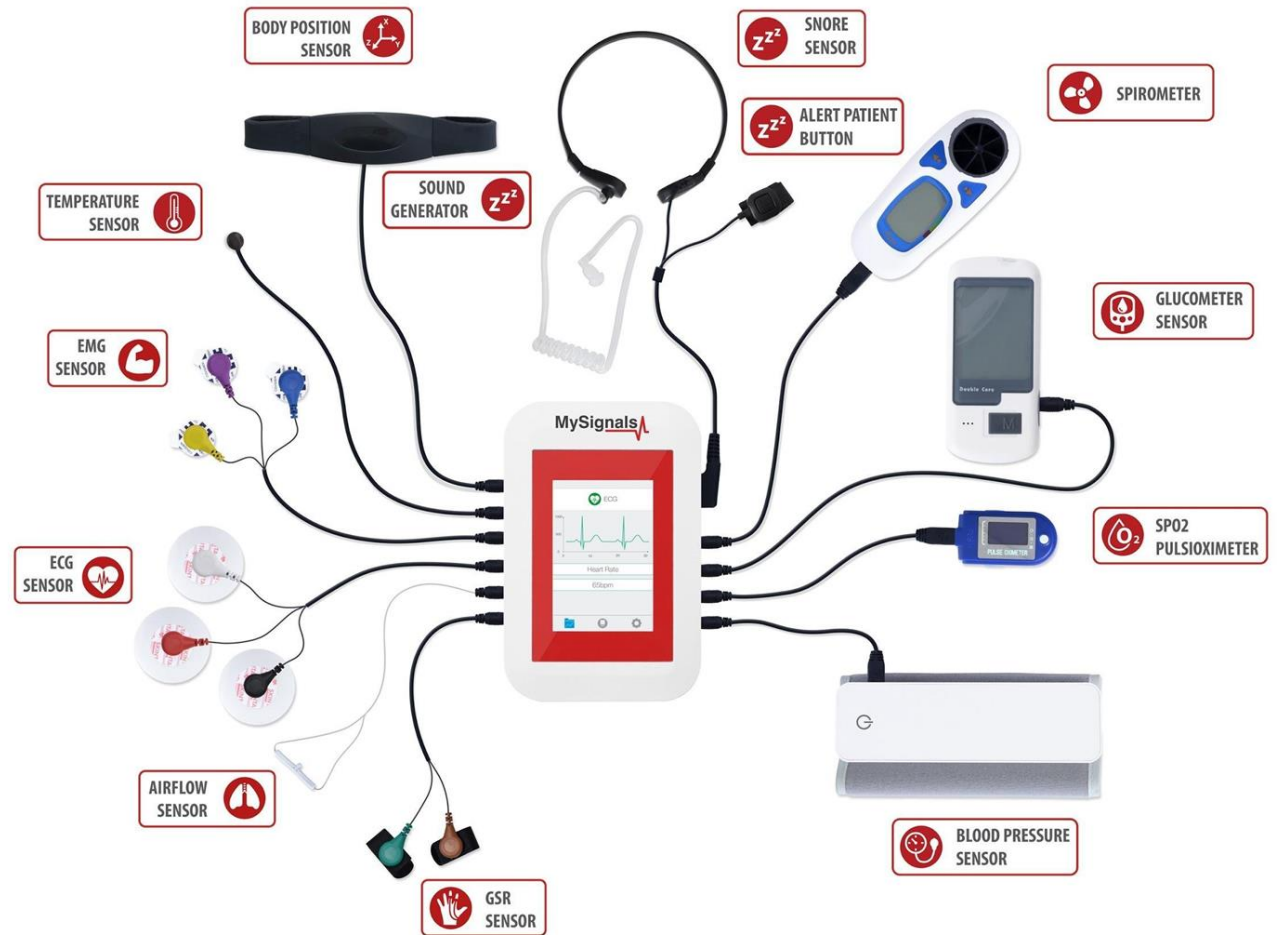

Similarities and differences among distinct tumors

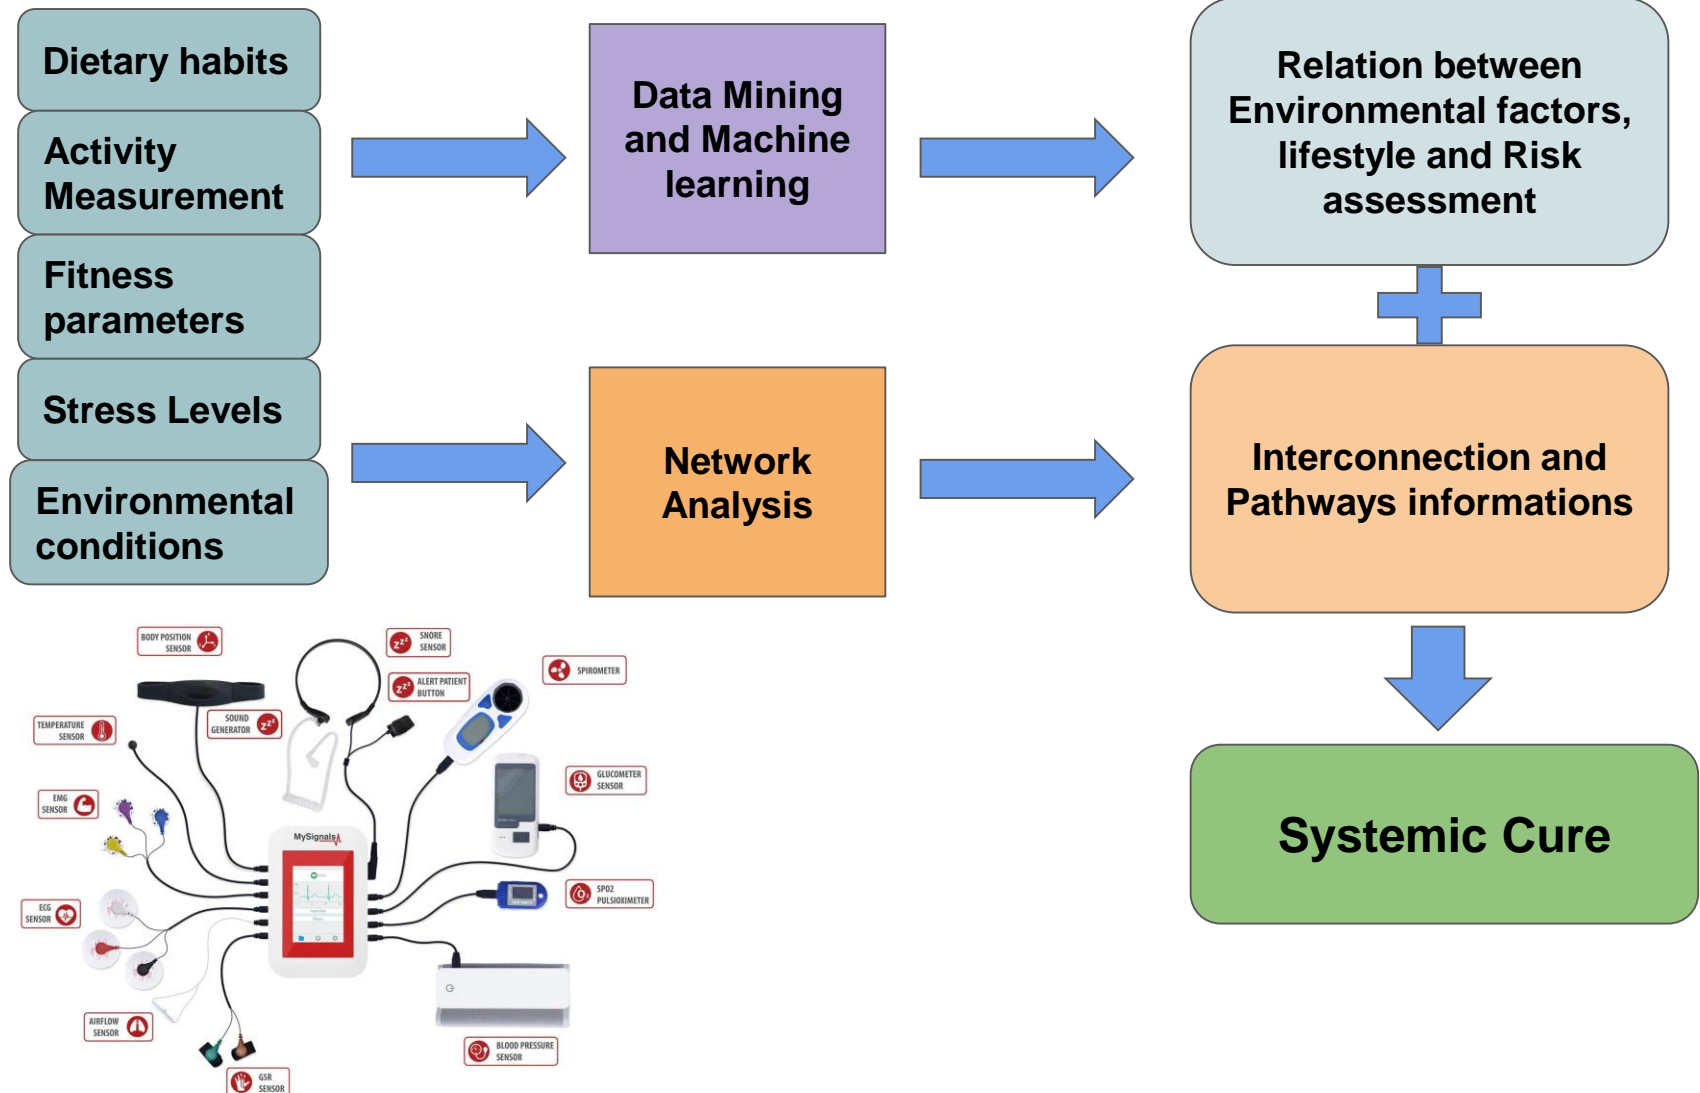

A similar impact can be studied with environmental factors using both data mining with feature extraction and network analysis

- Dietary habits
- Activity Measurement
- Fitness parameters
- Stress Levels
- Environmental conditions

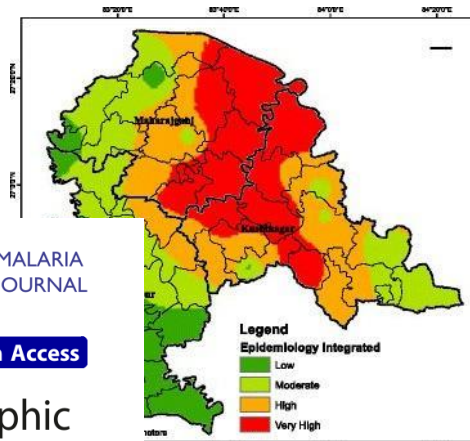

A similar impact can be studied with environmental factors using both data mining with feature extraction and network analysis

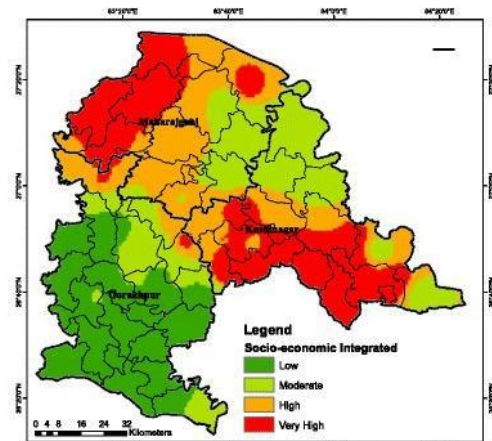

Socio-economic, epidemiological and geographic features based on GIS-integrated mapping to identify malarial hotspots

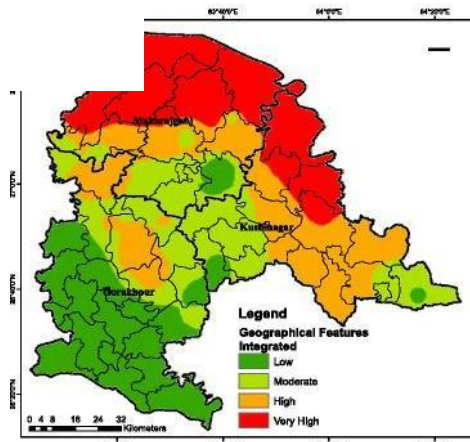

Abdul Qayum^{1,2}, Rakesh Arya³, Pawan Kumar^{4*} and Andrew M Lynn¹

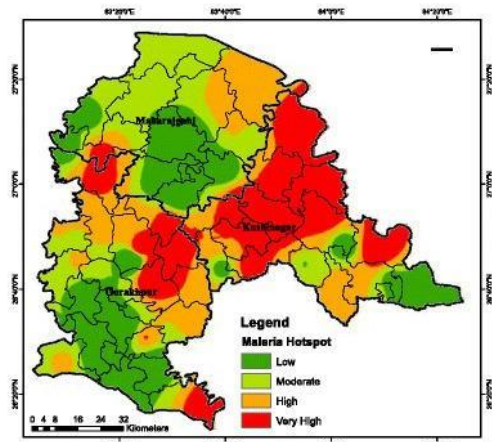

9.1: GIS integrated Epidemiology

9.2: GIS integrated Socio-economic

9.3: GIS integrated geographical features

9.4: GIS integrated Malarial hotspots

Integrated multiparameter data model for prediction of malaria hotspots

• 1. Socio-economic aspects

- Population, child population, literacy, and workforce participation

• 2. Epidemiology

- Annual parasitic index (API) and slides collected and examined)

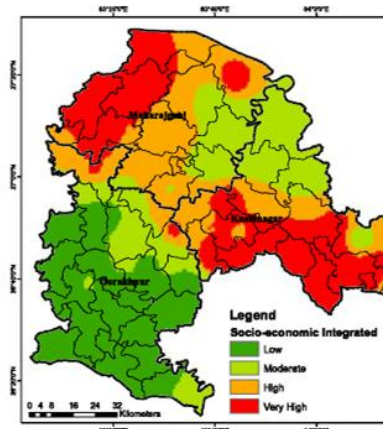

• 3. Geographical features

- Settlement, forest cover, water bodies, rainfall, relative humidity, and temperature

• *Malaria Journal*, 2014
